

# Logical Model

Anna Monreale

# Relational Data Model

- Starting from the output of the Analysis of user requirements: **the Class Diagram**
- Generate the Logical Model by following a systematic process
  - organizing all data in flat **tables** of **rows** with a primary key
  - transforming associations as **foreign keys**

<i>Employees</i>			
<i>Code</i>	<i>Name</i>	<i>Salary</i>	<i>Dept</i>
232	John	1000	Y1
143	Mary	1200	X2
254	Joan	900	Y1

<i>Departments</i>	
<i>Code</i>	<i>Budget</i>
Y1	100000
X2	750000

# Algorithm for the Logical Design

- **Step I:** Translate all classes which are not involved in hierarchy
- **Step II:** Translate all hierarchies
- **Step III:** Translate multivalued attributes in to tables
- **Step IV :** Translate N-N relationships
- **Step V :** Translate 1-N relationships
- **Step VI :** Translate 1-1 relationships
- **Step VII :** Add other possible constraints

# Step I: Translate all classes

- Classes become **tables** containing
  - Attributes
  - primary key
  - foreign keys
- **Primary key**
  - Simple to be used and compact
  - We can use set of attributes if compact
  - We can use a synthetic identifier

<b>Students</b>	T
studentID INTEGER	PK
Surname CHAR(20)	
Name CHAR(20)	
Year INTEGER	
Program CHAR(20)	
Supervisor CHAR(4)	FK

<b>Teacher</b>	T
code CHAR(4)	PK
...	

# Step I: Translate all classes

ASD	Algorithms	Bachelor
DB1	Databases	Master

# Step I: Translate all classes

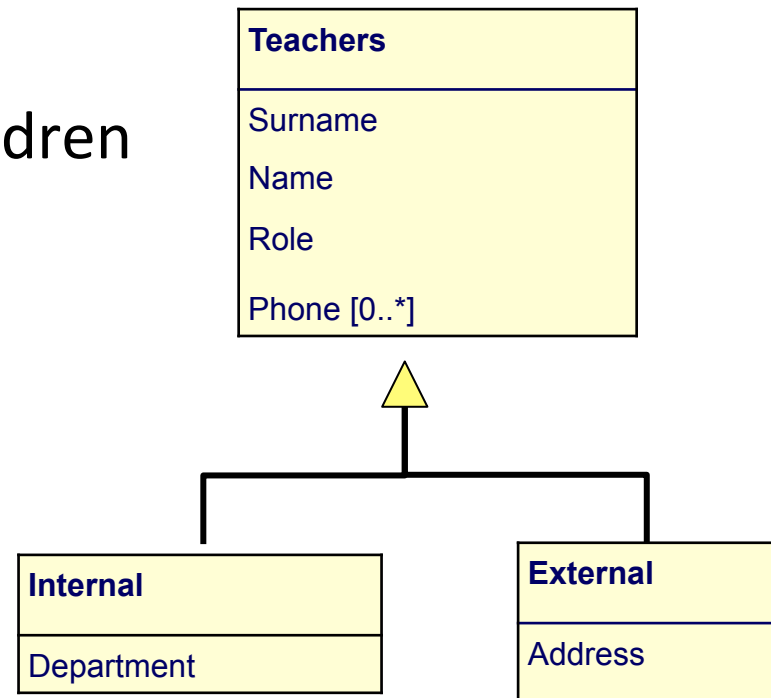

Stages
location
Date-start
duration

Stages	T
studentID INTEGER	PK, FK
Location CHAR(20)	
Date-start DATE	
Duration INTEGER	

<u>StudentID</u>	Location	Date-start	Duration
444	Microsoft	2002-05-15	3
77777	Microsoft	2002-05-15	3
88888	Basica	2002-09-01	3

# Step II: Translate all hierarchies

- Relational Data Model does not have Hierarchies
- Three possible cases
  - Translate only the parent class
  - Translate only children
  - Translate both parent and children

# Step II: Translate all hierarchies

- **Translate only the parent class**
  - One table with the name of the parent class
  - The table contains the attributes of both parent and children
  - Add an attribute **TYPE** to distinguish the instance
  - Generation of **NULL values**
  - It is convenient if the children **are not used so much** in the application

<b>Teachers</b>	<b>T</b>
<b>Code CHAR(4)</b>	<b>PK</b>
<b>Surname CHAR(20)</b>	
<b>Name CHAR(20)</b>	
<b>Department CHAR(10)</b>	
<b>Role CHAR(15)</b>	
<b>Address CHAR(20)</b>	
<b>Type CHAR(10)</b>	

# Step II: Translate all hierarchies

- **Translate only children classes**
  - One table for each child
  - Each child table inherits both attributes and relationships of the parent
  - Possible only when the the **hierarchy is complete**
  - It is convenient if the application **uses often the children**

<b>InternalTeachers</b>	<b>T</b>
<b>Code CHAR(4)</b>	<b>PK</b>
<b>Surname CHAR(20)</b>	
<b>Name CHAR(20)</b>	
<b>Department CHAR(10)</b>	
<b>Role CHAR(15)</b>	

<b>ExternalTeachers</b>	<b>T</b>
<b>Code CHAR(4)</b>	<b>PK</b>
<b>Surname CHAR(20)</b>	
<b>Name CHAR(20)</b>	
<b>Address CHAR(10)</b>	
<b>Role CHAR(15)</b>	

# Step II: Translate all hierarchies

- Translate both parent and children classes
  - One table for each child and for the parent
  - Each class has its attributes
  - It is necessary if the application **uses often both children and parent**

Teachers	T
Code CHAR(4)	PK
Surname CHAR(20)	
Name CHAR(20)	
Role CHAR(15)	

ExternalTeachers	T
Code CHAR(4)	PK,FK
Address CHAR(10)	

InternalTeachers	T
Code CHAR(4)	PK,FK
Department CHAR(10)	

# Step III: Translate multivalued attributes

- Each multivalued attribute generates a new table
- The new table containing a foreign key vs the original class

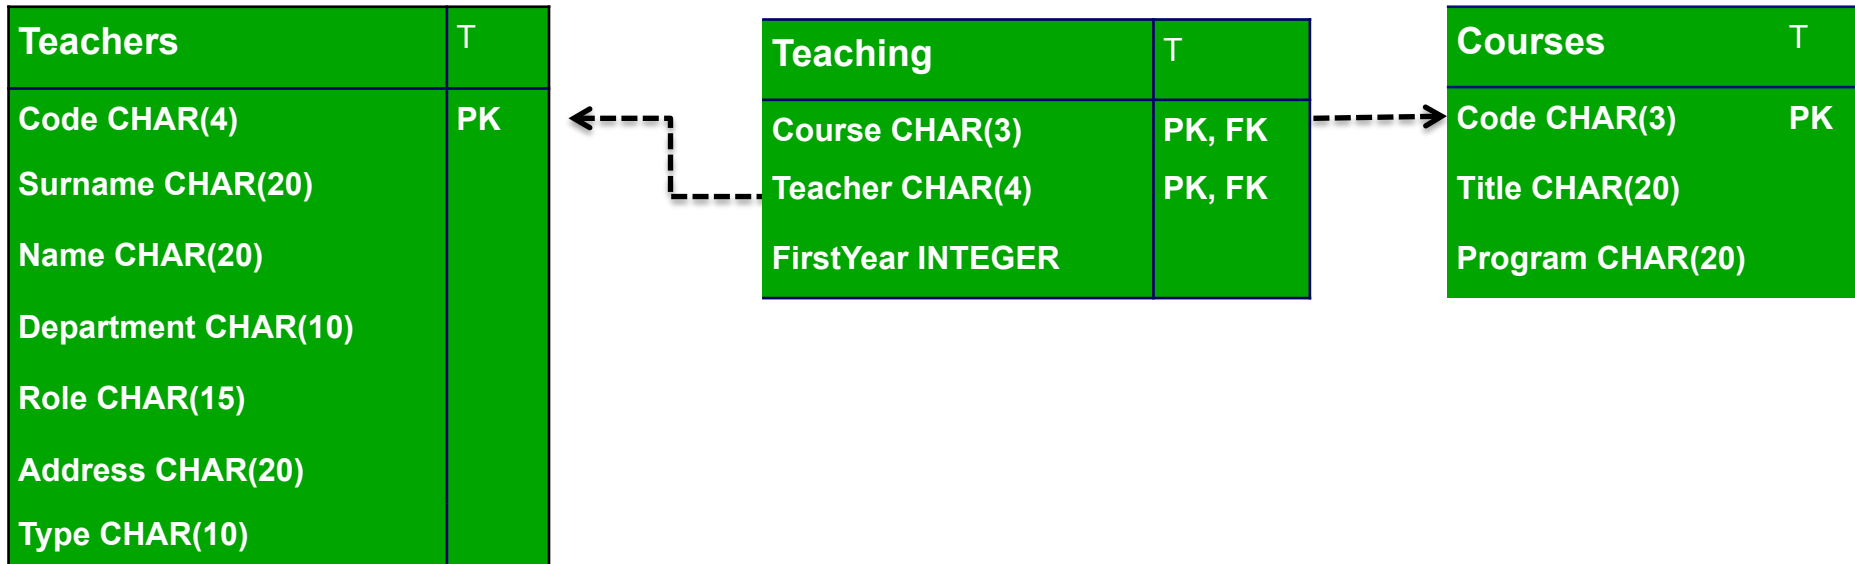

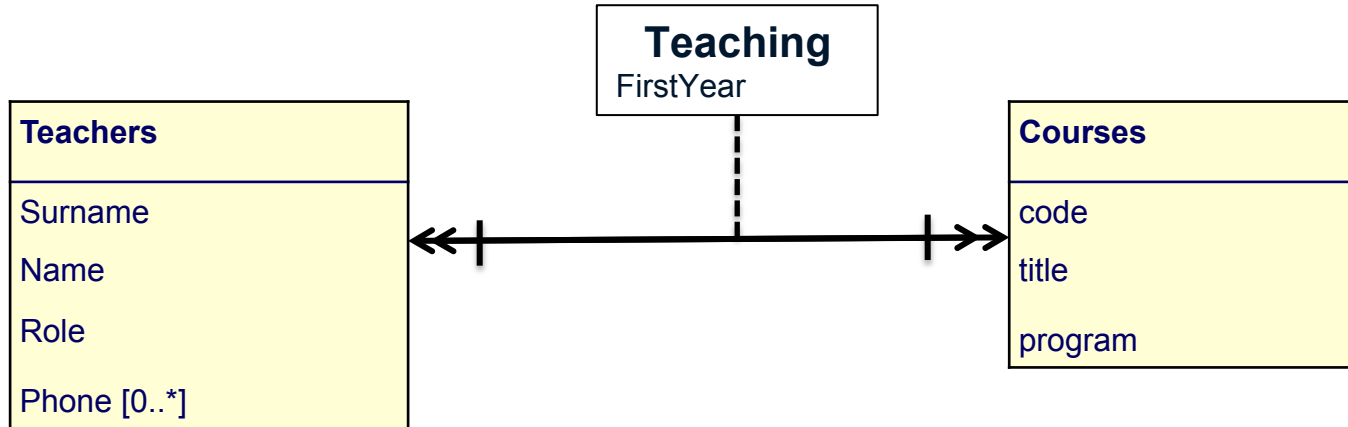

Teachers
Surname
Name
Role
Phone [0..*]

Teachers	T
Code CHAR(4)	PK
Surname CHAR(20)	
Name CHAR(20)	
Department CHAR(10)	
Role CHAR(15)	
Address CHAR(20)	
Type CHAR(10)	

Phones	T
Number CHAR(15)	PK
Teacher CHAR(4)	FK

# Step IV : Translate N-N relationships

# Step IV : Translate N-N relationships

<u>codice</u>	cognome	nome	...

# Step V : Translate 1-N relationships

<b>Exams</b>	T
Code CHAR(5)	PK
Course CHAR(3)	FK
Mark INTEGER	
Laud BOOL	
Date DATE	

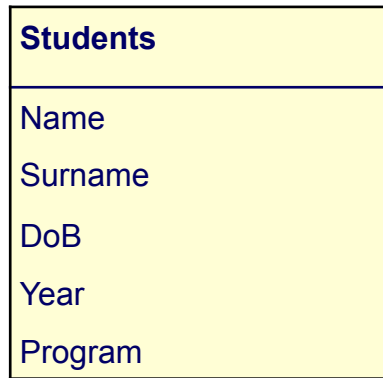

<b>Courses</b>	T
Code CHAR(3)	PK
Title CHAR(20)	
Program CHAR(20)	

<u>Code</u>	Title	Program
PR1	Programming	Bachelor
ASD	Algorithms	Bachelor
DB1	Databases	Master

<u>Code</u>	Course	Mark	Laud	Date
pr101	PR1	27	false	2002-06-12
asd01	ASD	30	true	2001-12-03
BD101	INFT	24	false	2001-09-30
pr102	PR1	21	false	2002-06-12
asd02	ASD	20	false	2001-12-03
asd03	ASD	28	false	2002-06-13

# Step VI : Translate 1-1 relationships

- Similar to 1-N relationship but we can choose where putting the foreign key
- It is better in the class where we have total relationship

Students	T
studentID INTEGER	PK
Surname CHAR(20)	
Name CHAR(20)	
Year INTEGER	
Program CHAR(20)	
Supervisor CHAR(4)	FK

Stages	T
studentID INTEGER	PK, FK
Location CHAR(20)	
Date-start DATE	
Duration INTEGER	

# Step VII: Add other possible constraints

- Now we have:
  - Tables
  - Attributes
  - Primary keys
  - Foreign keys
- We need to add other constraints
  - NOT NULL
  - DEFAULT
  - CASCADE
  - CHECK
  - .....
