DATA MINING 2 Time Series – Matrix Profile, Motifs & Discords

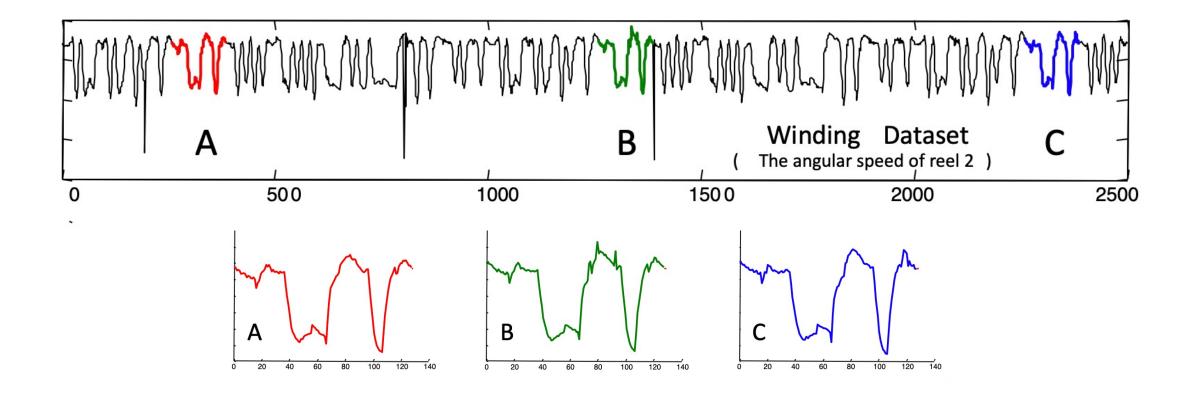

Riccardo Guidotti

a.a. 2022/2023

Time Series Motif Discovery

- Finding repeated patterns, i.e., pattern mining.
- Are there any repeated patterns, of length *m* in the TS?

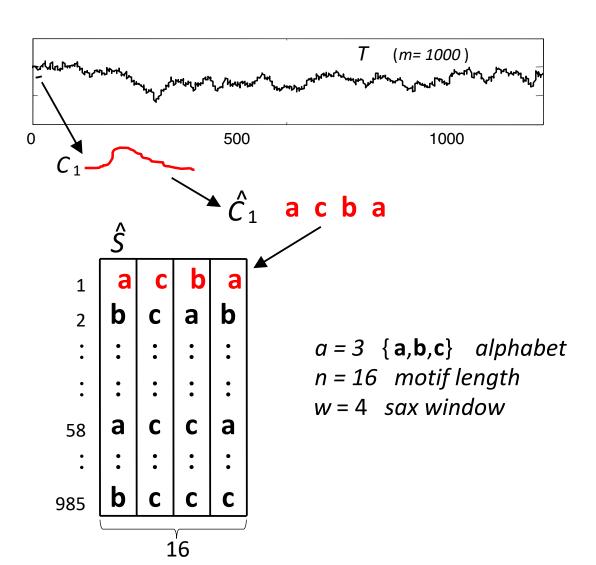

Why Finding Motifs?

- Mining **association rules** in TS requires the discovery of motifs. These are referred to as primitive shapes and frequent patterns.
- Several **TS classifiers** work by constructing typical prototypes of each class. These prototypes may be considered motifs.
- Many TS anomaly detection algorithms consist of modeling normal behavior with a set of typical shapes (which we see as motifs) and detecting future patterns that are dissimilar to all typical shapes.

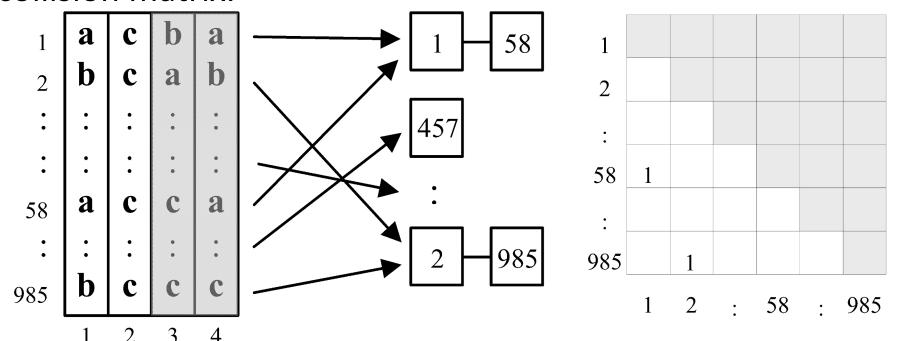

How do we find Motifs?

- Given a predefined motif length m, a brute-force method searches for motifs from all possible comparisons of subsequences.
- It is obviously very slow and computationally expensive.
- The most referenced algorithm is based on a hot idea from bioinformatics, random projection* and the fact that SAX allows use to lower bound discrete representations of TSs.
- J Buhler and M Tompa. Finding motifs using random projections. In RECOMB'01, 2001.

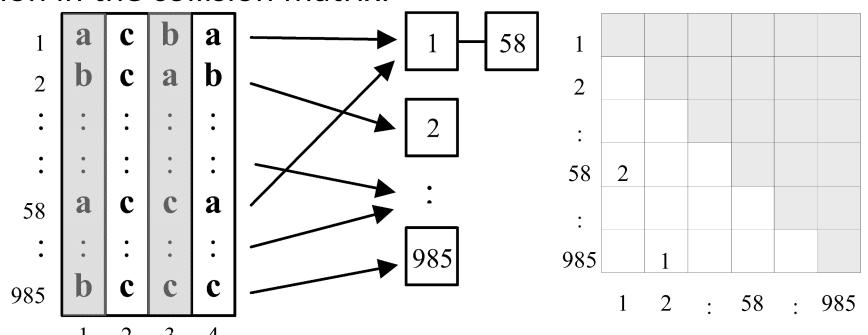

Assume that we have a time series T of length 1,000, and a motif of length 16, which occurs twice, at time T₁ and time T₅₈.

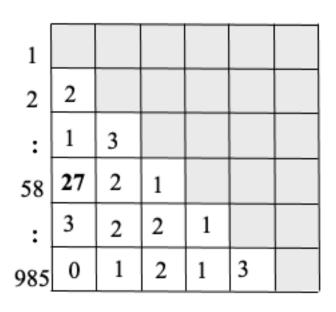

- A mask {1,2} was randomly chosen, so the values in columns {1,2} were used to project matrix into buckets.
- Collisions are recorded by incrementing the appropriate location in the collision matrix.

- A mask {2,4} was randomly chosen, so the values in columns {2,4} were used to project matrix into buckets.
- Once again, collisions are recorded by incrementing the appropriate location in the collision matrix.

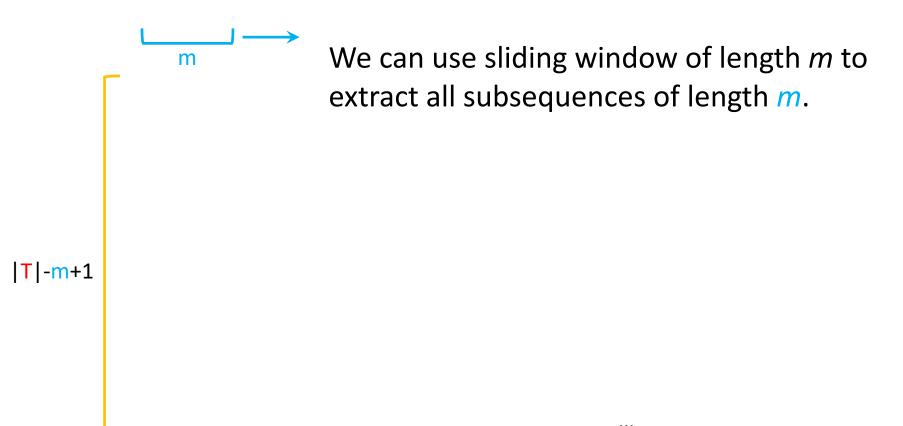

- At the end of the random perturbations consider the motifs observing the matrix in decreasing order of occurrences.
- For instance, this matrix indicates a high chance of having a motif staring at positions 1 and 58.
- The problem with this approach is that it is highly dependent from the approximation technique adopted.

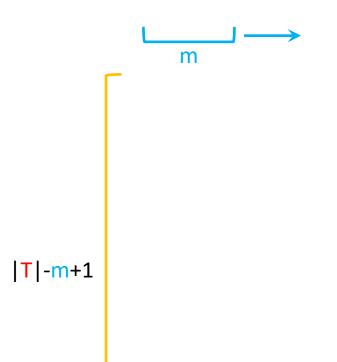

1 2 : 58 : 985

- The Matrix Profile (MP) is a data structure that annotates a TS and can be exploited for many purposed: e.g. efficient Motif Discovery.
- Given a time series, T and a desired subsequence length, m.

m

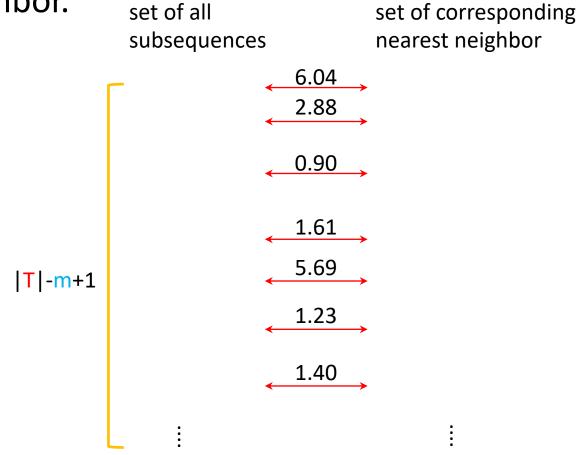

We can then compute the pairwise distance among these subsequences.

0	7.6952	7.7399	
7.6952	0	7.7106	•••
7.7399	7.7106	0	

...

• For each subsequence we keep only the distance with the closest nearest neighbor.

set of corresponding

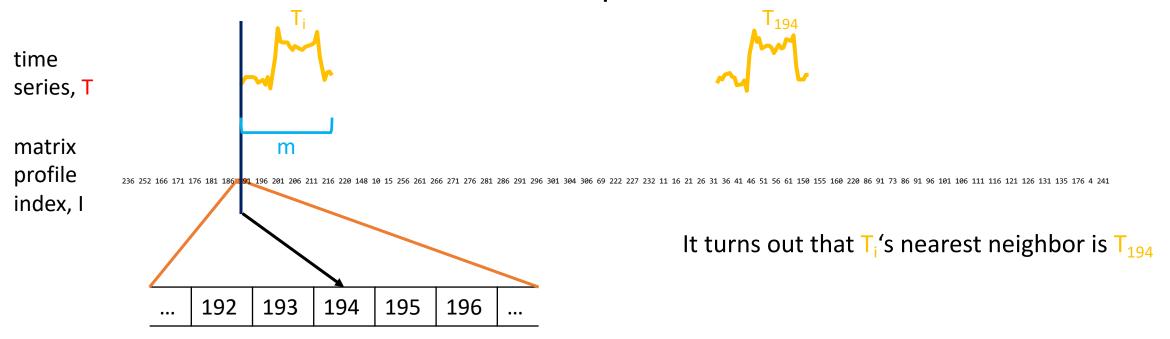

• The distance to the corresponding nearest neighbor of each subsequence can be stored in a vector called **matrix profile P**.

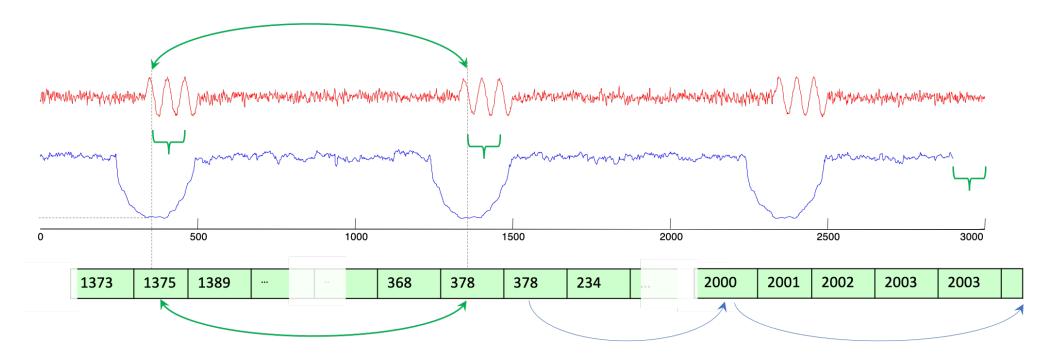

The matrix profile value at location i is the distance between T_i and its nearest neighbor

 The index of corresponding nearest neighbor of each subsequence is also stored in a vector called matrix profile index.

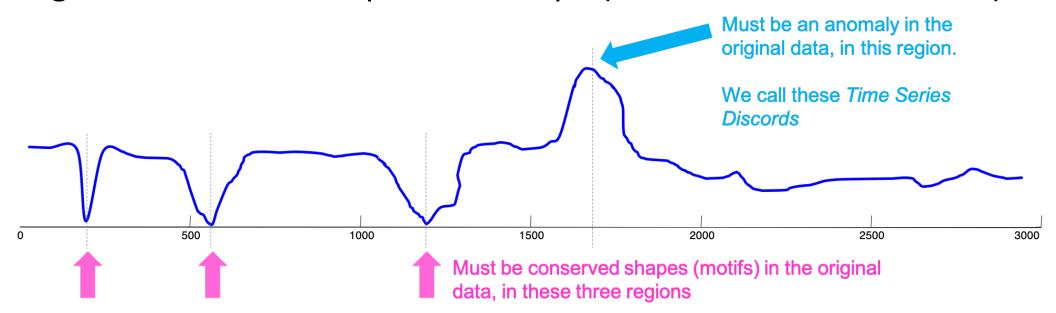

The matrix profile value at location i is the distance between T_i and its nearest neighbor

- The MP index allows to find the nearest neighbor to any subsequence in constant time.
- Note that the pointers in the matrix profile index are not necessarily symmetric.
- If A points to B, then B may or may not point to A
- The classic TS motif: the two smallest values in the MP must have the same value, and their pointers must be mutual.

How to "read" a Matrix Profile

- For relatively low values, you know that the subsequence in the original TS must have (at least one) relatively similar subsequence elsewhere in the data (such regions are "motifs")
- For relatively high values, you know that the subsequence in the original TS must be unique in its shape (such areas are anomalies).

Given a time series, T and a desired subsequence length, m.

m

Matrix profile is initialized as inf vector

This is just a toy example, so the values and the vector length does not fit the time series shown above

Given a time series, T and a desired subsequence length, m.

	inf																		
--	-----	-----	-----	-----	-----	-----	-----	-----	-----	-----	-----	-----	-----	-----	-----	-----	-----	-----	-----

At the first iteration, a subsequence T_i is randomly selected from T

Given a time series, T and a desired subsequence length, m.

We compute the distances between T_i and every subsequences from T (time complexity = $O(|T|\log(|T|))$) We then put the distances in a vector based on the position of the subsequences

3	2	0	5	3	4	5	1	2	9	8	4	2	3	4	8	6	2	1
	l			l											l			1

Given a time series, T and a desired subsequence length, m.

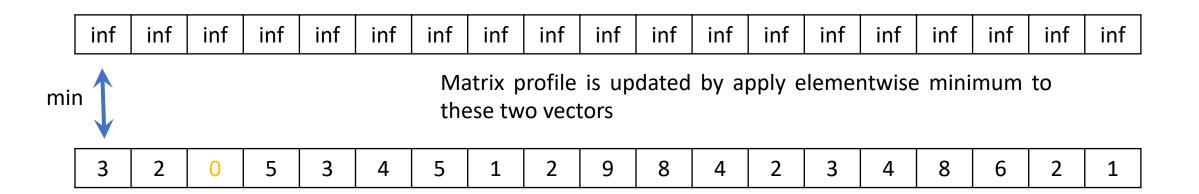

m

We compute the distances between T_i and every subsequences from T (time complexity = $O(|T|\log(|T|))$) We them put the distances in a vector based on the position of the subsequences

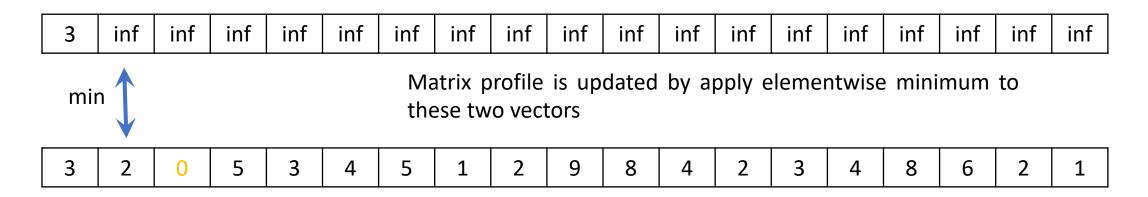

3	2	0	5	3	4	5	1	2	9	8	4	2	3	4	8	6	2	1
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

Let say T_i happen to be the third subsequences, therefore the third value in the distance vector is 0

Given a time series, T and a desired subsequence length, m.

ſ	3	2	inf	5	3	4	5	1	2	9	8	4	2	3	4	8	6	2	1
- 1																			

After we finish update matrix profile for the first iteration

3	2	0	5	3	4	5	1	2	9	8	4	2	3	4	8	6	2	1
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

Given a time series, T and a desired subsequence length, m.

m

3	2	inf	5	3	4	5	1	2	9	8	4	2	3	4	8	6	2	1
																		ı

In the second iteration, we randomly select another subsequence T_j and it happens to be the 12^{th} subsequences

Given a time series, T and a desired subsequence length, m.

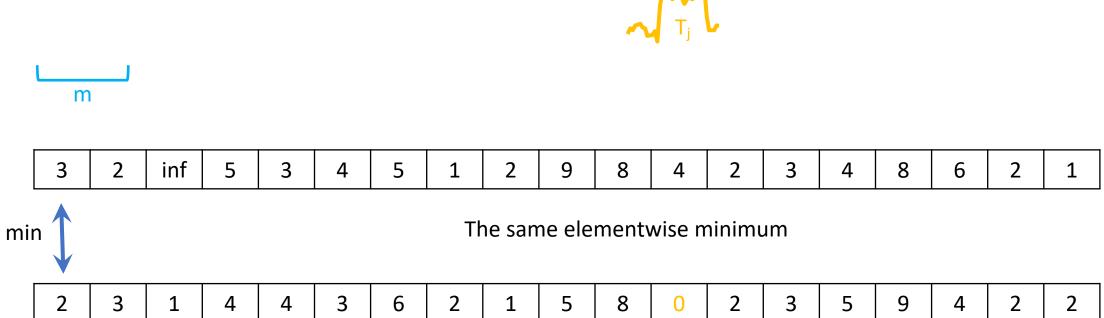

m

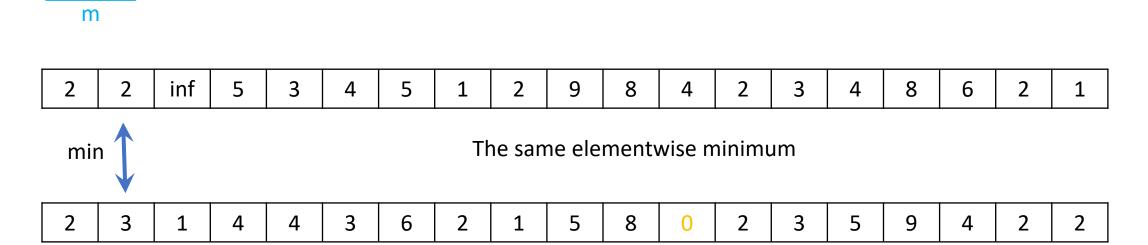

Once again, we compute the distance between T_i and every subsequences of T

2	3	1	4	4	3	6	2	1	5	8	0	2	3	5	9	4	2	2
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

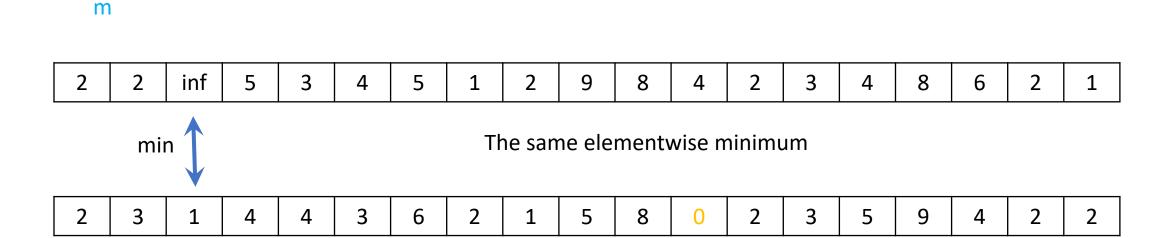

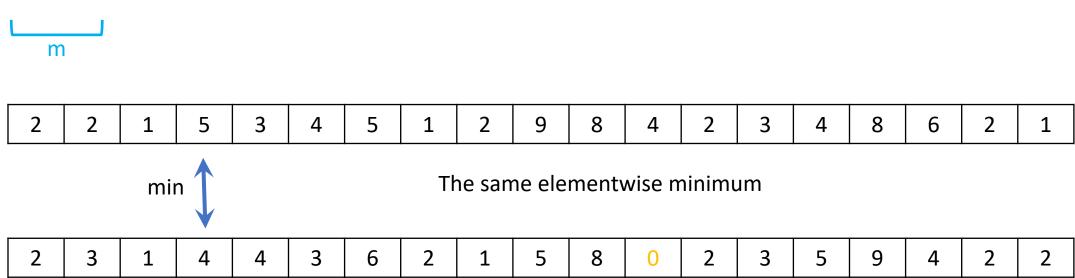

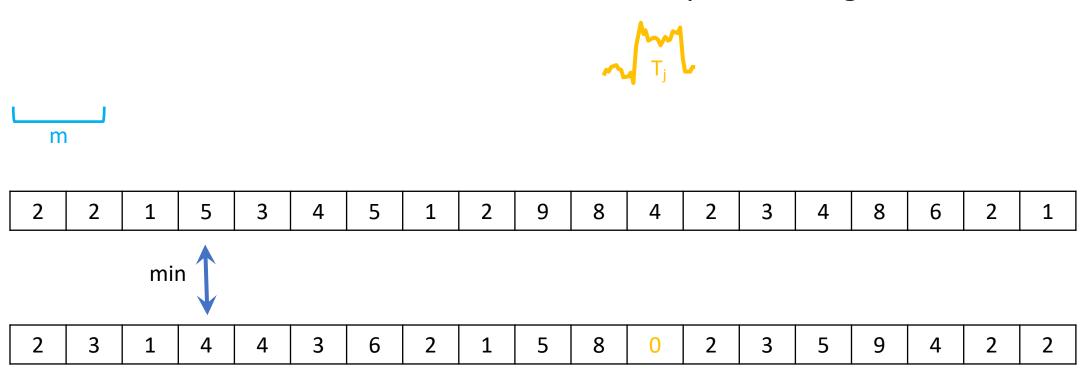

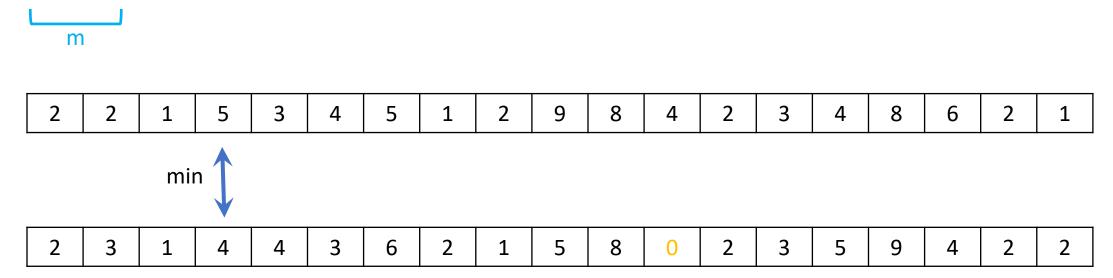

Given a time series, T and a desired subsequence length, m.

We repeat the two steps (distance computation and update) until we have used every subsequences. The different indexes are analyzed in parallel and the distance is calculated using the Mueen's Algorithm for Similarity Search (MASS) https://www.cs.unm.edu/~mueen/FastestSimilaritySearch.html

Given a time series, T and a desired subsequence length, m.

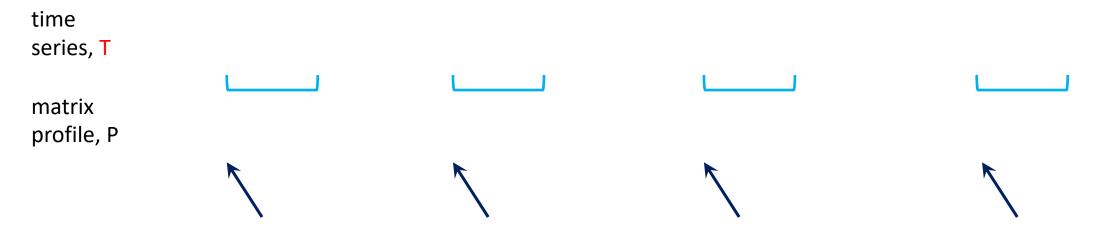

There are |T| subsequences and the distance computation is $O(|T|\log(|T|))$

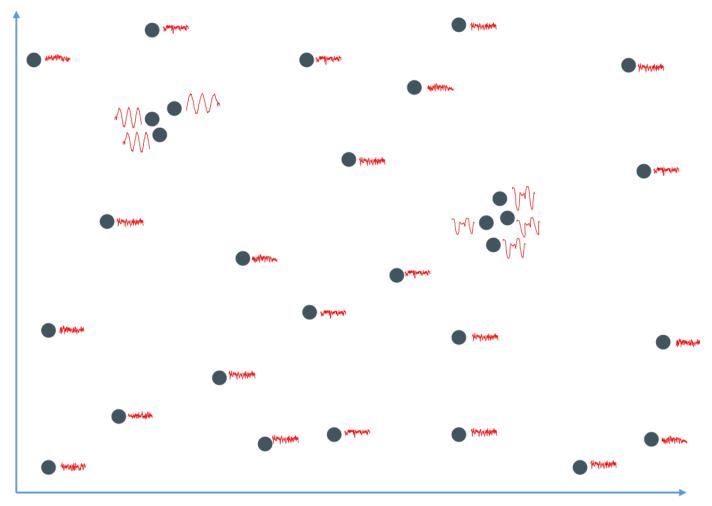

The overall time complexity is $O(|T|^2 \log(|T|))$

Motif Discovery From Matrix Profile

Local minimums are corresponding to motifs

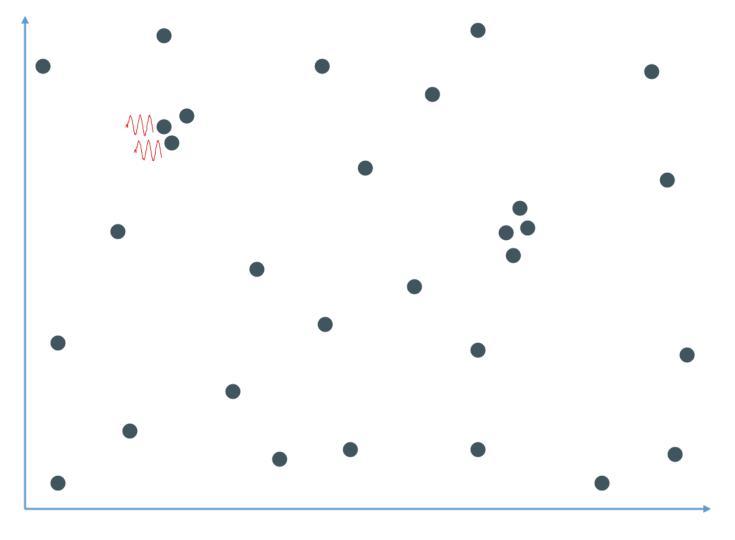

Motif Discovery From Matrix Profile

- It is sometime useful to think of time series subsequences as points in m-dimensional space.
- In this view, dense regions in the m-dimensional space correspond to regions of the time series that have a low corresponding MP.

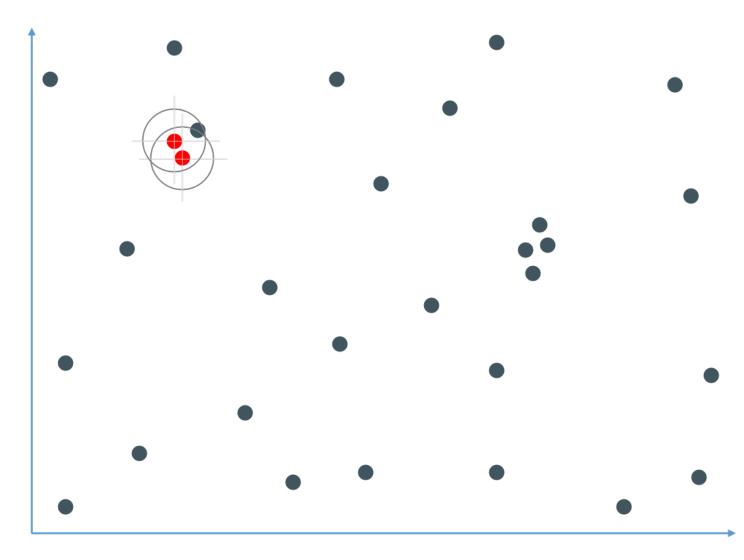

Top-K Motifs

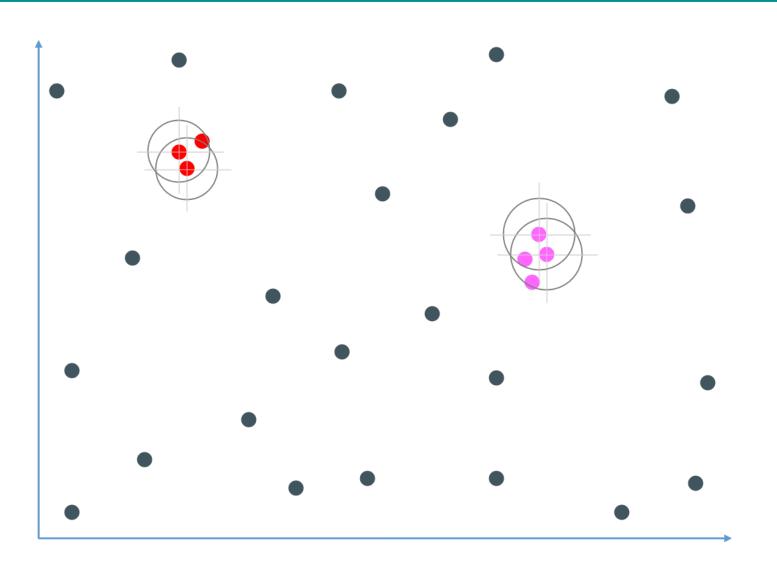

- We need a parameter R.
- 1 < R < (small number, say 3)
- Let's make R = 2 for now.
- We begin by finding the nearest pair of points, the motif pair....
- This the pair of subsequences corresponding to lowest pair of values in the MP

Top-K Motifs

- We find the nearest pair of points are D1 apart.
- Let's draw a circle, D1 times R, around both points.
- Any points that are within either of these circles, are added to this motif, in this case just one.
- The Top-1 motif has three members, it is done.

Top-K Motifs

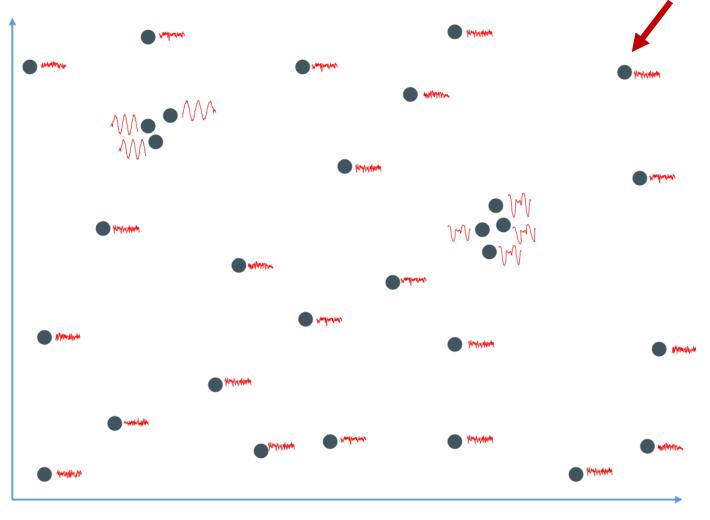

- Now lets find the Top-2 motif.
 We find the nearest pair of
 points, excluding anything from
 the top motif.
- The nearest pair of points are D2 apart.
- Lets draw a circle D2 times R, around both points.
- Any points that are within either of these circles, is added to this motif, in this case there are two for a total of four items in the Top-2 Motif

Top-K Motifs

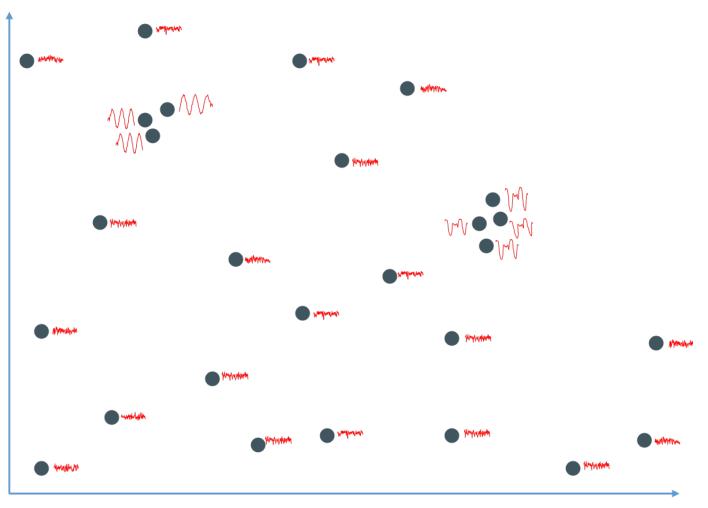

- We are done with the Top-2 Motif
- Note that we will always have:
 - $D_1 < D_2 < D_3 ... D_K$
- When to stop? (what is K?)
- We could use MDL or a predefined K.

Anomaly Discovery From Matrix Profile

- We need a parameter E of subsequences to exclude in the vicinity of the anomaly.
- Lets make E = 2 for now.
- We begin by finding the subsequence with the highest distance in the MP
- This corresponding to biggest anomaly

Top-K Anomaly

- Then we look for the E closest subsequences to the anomaly.
- We remove all of them.
- We can use a predefined K or the MDL to stop.

. INTRODUCTION

In INTRODUCTION
While the last decade has seen a lurge interest in time series classification, to date the most accurate and robust method is the simple nearest neighbor algorithm [412][414]. While the nearest neighbor algorithm has the advantages of simplicity and not requiring extensive parameter tuning, it does have several important disadvantages. Chief among these are its space and time equirements, and the fact that it does not tell us anything about only a particular object was assigned to a particular class.

In this work we present a novel time series data mining primitive called *line neithe line* in the present the present the series series series subsequences which are is some sense maximally perpresentative of a class. While we believe thispelets can have many uses in data mining, one obvious implication of them is to mitigate the two weaknesses of the nearest neighbor algorithm noted algorithm to weaknesses.

appose we wish to build a classifier to distinguish thes plants; what features should we use? Since the intra-variability color and size within each class completely dwarfs the inte-

classification, clustering and outlier obectoon or snapes in receivers [8]. However, here we find that using a nearest neighboclassifier with either the (rotation invariant) Euclidean distance of Dynamic Time Warping (DTW) distance does not significant outperform random guessing. The reason for the pot performance of these otherwise very competitive classifiers seen. to be due to the fact that the data is somewhat noisy (i.e. insect bites, and different stem lengths), and this noise is enough to

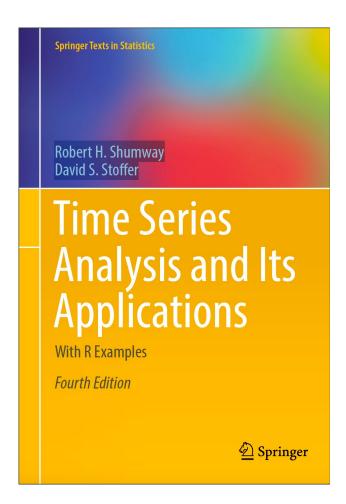

During the last two decades. Time Series Classification (TSC) has been considered as one of th most challenging problems in data mining (Yang and Wu, 2006; Esling and Agon, 2012). With the increase of temporal data availability (Silva et al., 2018), hundreds of TSC algorithms have been proposed since 2015 (Bagnall et al., 2017). Due to their natural temporal ordering, time series data are present in almost every task that requires some sort of human cognitive process (Längkvist et al., 2014). In fact, any classification problem, using data that is registered taking into account some notion of ordering, can be cast as a TSC problem (Cristian Borges Gamboa, 2017). Time series are encountered in many real-world applications ranging from electronic health records (Rajkomar et al., 2018) and human activity recognition (Nweke et al., 2018; Wang et al., 2018) to acoustic scene classification (Nwe et al., 2017) and cyber-security (Susto et al., 2018). In addition, the diversity of the datasets' types in the UCR/UEA archive (Chen et al., 2015b; Bagnall et al., 2017) (the largest repository of time series datasets) shows the different applications of the TSC problem

Exercises Matrix Profile

Given the TS $x = \langle 2, 1, 3, 4, 7, 5, 3, 4, 7, 5 \rangle$

- 1. Build the Matrix Profile for x with m=4 using the Manhattan distance as distance function between subsequences.
- 2. Draw the Matrix Profile
- 3. Identify the motifs with distance equals 0 and length equals to m
- 4. Which is a correct value for m that would have retrieved more motifs

with distance equals to 0?
